# LANL / J-4 Technology for IAEA Seals

## Spectral Interferometry

Mark M. Pickrell, J-4, LANL  
Steve Gilbertson, J-4, LANL

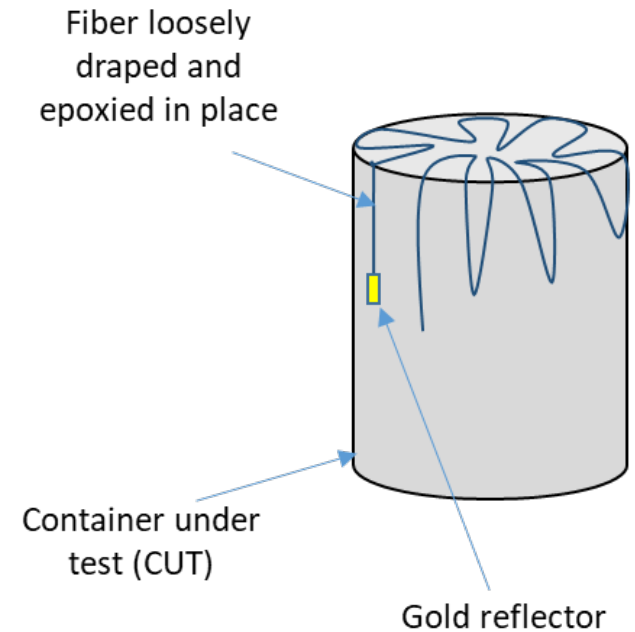

September 2020

Managed by Triad National Security for the U.S. Department of Energy's NNSA

# Problem Background

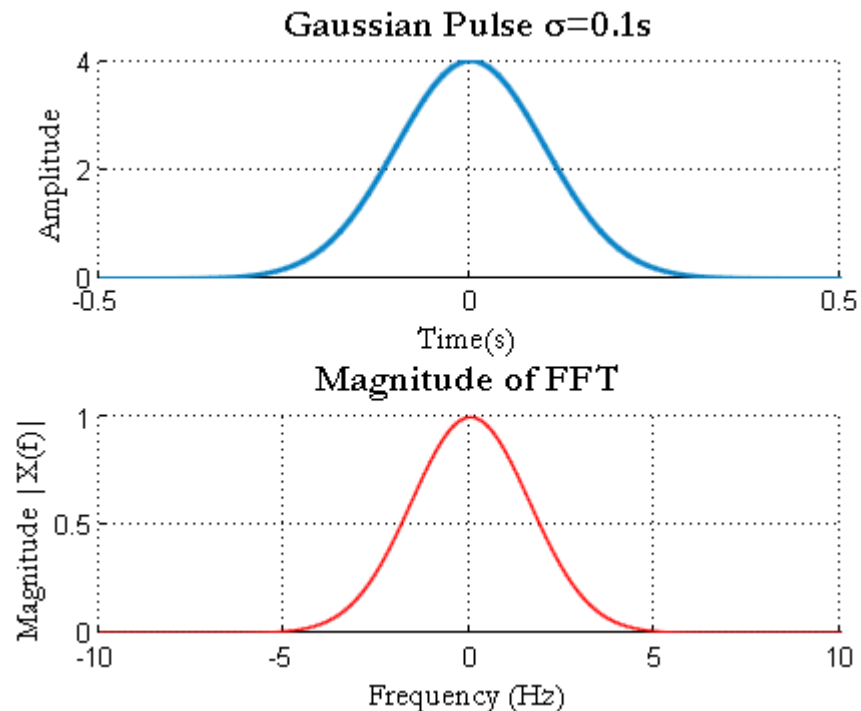

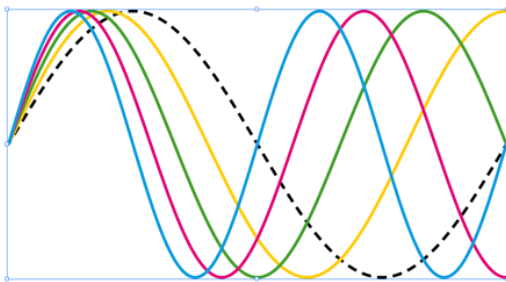

- Addressing the modernization of IAEA optical fiber seals, which are decades old technology.
- Existing optical fiber seals do not have an encoding of the light signals that could render them tamper-proof.

Schematic of  
fiber optic seal

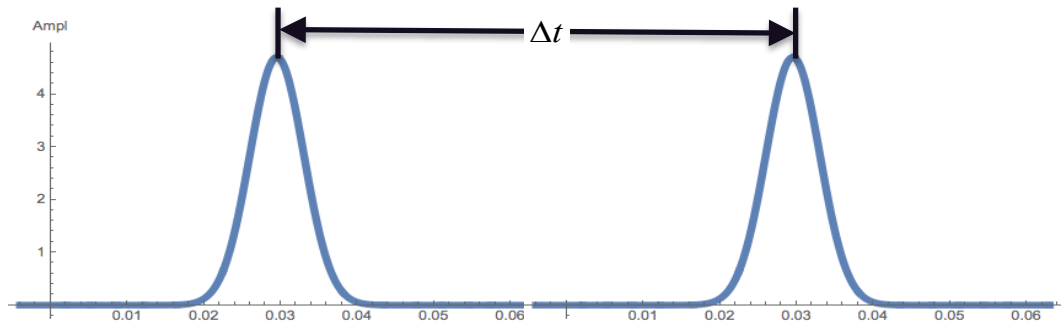

# Physics Background

- Based on wave mechanics
- A short duration laser pulse can be Fourier Transformed
- Gaussian in time  $\rightarrow$  Gaussian in wavelength
- So, mathematically represented as a set of sine waves of various amplitudes, but infinite duration in time.

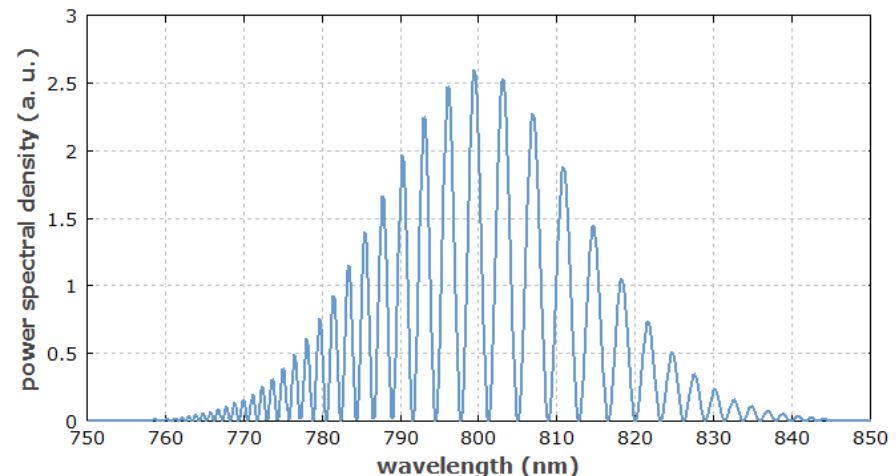

# Now Consider Two Laser Pulses

- Short duration.
- Reasonably close in time, but **not** overlapping in time.

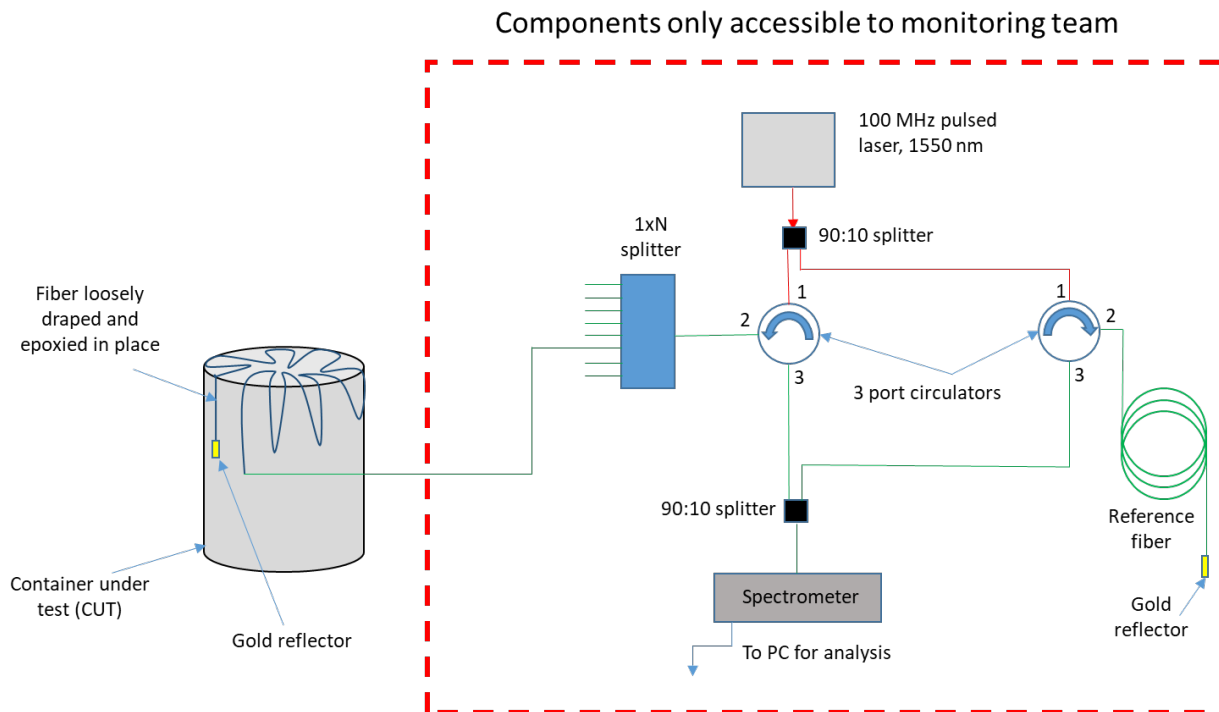

- The Fourier Transform becomes: 
- The pulses interfere spectrally in the wavelength domain!
  - The reason is the Fourier Transform components of the second pulse are phase shifted by:

$$\Delta\phi_\omega = \omega\Delta t$$

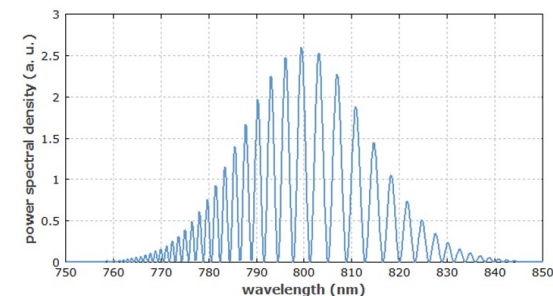

# Now Consider a Basic Fiber Interferometer

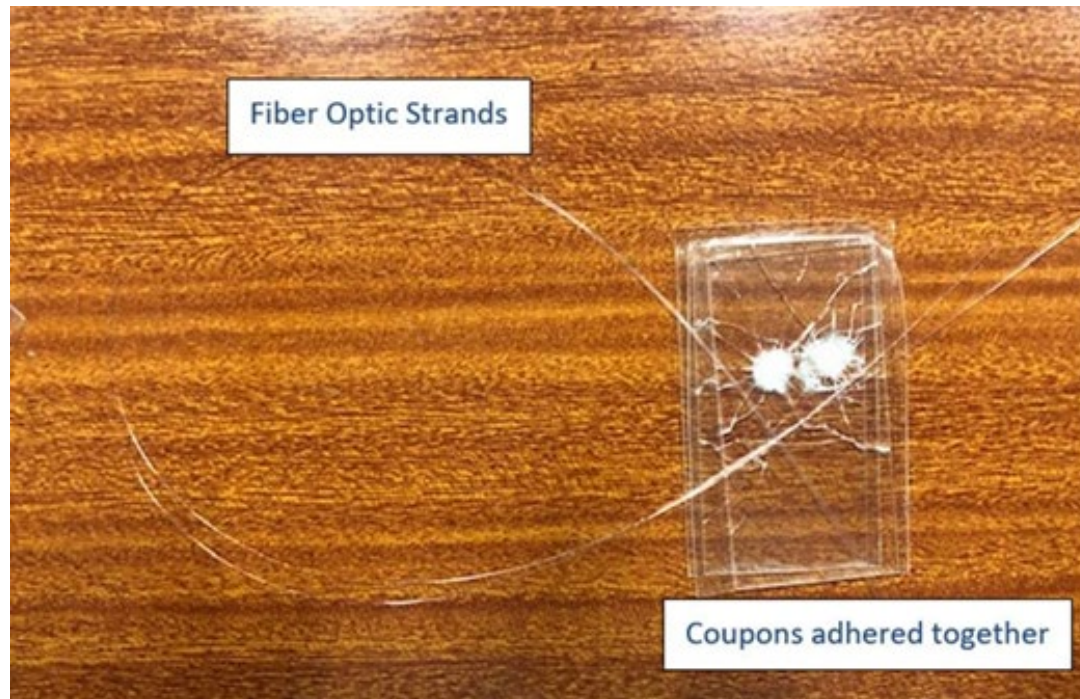

- Two closely timed pulses from a single laser pulse because beam is split and recombined. Lengths of reference and test legs are close, but not identical

Qualitatively produces the same spectral interferogram.

## Now Consider Replacing Gold Reflector on Test Fiber With:

- **Damages fiber at multiple locations, which creates multiple reflections at:**
  - Different amplitudes and
  - Slightly different times
- **All spectrally interfere with each other and the reference pulse.**

# The Resulting Spectrum:

- Very complicated spectrum.
- For, say, 10 reflected pulses, there are:  $C = \binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{11!}{2!9!} = 55$   
combinations of one pulse with another
- Each of these produce a unique spectrum, then all then superpose → 55 individual spectra superposed.
- Very difficult to duplicate with a ersatz fiber, especially when the reference leg length, the spectrometer resolution, and the laser pulse width are all unknown.
- Further, the amplitude of the reflections vary depending on the fiber damage.

# Application Summary

- **Laser / optical components are all COTS, (telecommunications technology).**
- **Similar configuration is already at use at DARHT / J-4 for vessel strain measurements as the: Spectral Interferometry for Transient Strain (SITS)**
- **Nominal production cost for this system would be ~\$50k**
  - With time multiplexer, could service 50 – 100 separate containers
- **Applications are:**
  - Classical IAEA Seals
